PREFACE

This report represents the latest in a series of demographic projections undertaken by the Institute of Public Affairs under contract with the Nova Scotia Department of Development. Following each Census of Canada since 1966, the Institute has provided age and sex-specific projections of the population of Nova Scotia, disaggregated to the county level. The present report also includes projections of households and families at the county level.

The set of projections presented here is considered at this moment to be a reasonable one, provided that the assumptions upon which it is based continue to be valid. Other projection efforts, employing other assumptions, may result in different values than those derived here. Further, when planning is designed to alter present trends it will, if successful, lead to actual populations which will differ from those projected in this report.

The cooperation and assistance of Paul Dober and Heather MacMullin of the Statistics & Research Services Branch, Nova Scotia Department of Development is gratefully acknowledged. Doreen Liew built the computer model utilized to perform the projections and provided advice and assistance in all phases of the research.

A Technical Appendix which provides more detailed information on the methodology and the computer model employed to derive the projections contained in this report is available from the Statistics & Research Services Branch, Nova Scotia Department of Development.

PART ONE - POPULATION PROJECTIONS

Introduction

Reliable projections of population are widely recognized to be valuable planning tools which may be utilized by both the public and the private sectors. Such projections indicate important future demands for numerous types of facilities, services, and programmes. Some of the areas in which these projections may have utility include: economic development and planning; the provision of adequate transportation systems; demand for employment and housing; school, hospital, and other institutional planning; the provision of health, welfare, and recreational services and facilities; and the supply of various goods and services to individuals and population sub-groups. In certain of these instances, the determination of the age and sex composition of the population is as important as the population total.

The population projections presented in this report are an attempt to provide users with adequate information on which to base decisions on future plans and programmes. Projected total populations, by sex, are presented for Nova Scotia's 18 counties, for the Halifax Census Metropolitan Area (CMA), and for the Province at each year of the projection period (1982-1991) in Table 6. Five-year age-specific projections are presented for the years 1984 to 1986, and 1991 (Table 8). Note that in all cases provincial totals were obtained by summing the results for the 18 individual counties.

Historical Background

Since any projections must be made in light of previous experience, the historical population for Nova Scotia is presented by county for the census years from 1901 to 1981 (Table 1). Totals for regions of the province are also presented.

Births, deaths, and net migration for each county for the interval 1976-1981 are presented in Table 2. Net migration was obtained as a residual: population increase - (births - deaths).

Nova Scotia totals for the three components of population change for the 1976-1981 period were determined by aggregating the individual county values.

[b]Calculated as a residual: population increase - (births-deaths).

General Projection Methodology[1]

The projections contained in this report are based upon a cohort-survival methodology, which takes into account the separate calculation of the three components of population change: fertility, mortality, and net migration. In this technique appropriate age-specific survival rates, by sex, and age-specific fertility rates are applied to the base population distributed by age and sex to determine the expected population. The expected population is then multiplied by the appropriate net migration rates to calculate the actual population for each year. The basic calculation can be expressed by the following equation:

$$Pe = Pc + B - D + NM$$

where:

Pe = estimated population

Pc = base (census) population

B = live births

D = deaths

NM = net migration

---

[1] A Technical Appendix which provides a more detailed discussion of the methodology and the computer model employed to carry out the projections contained in this report is available from the Statistics & Research Services Branch, Nova Scotia Department of Development.

The above procedure can be illustrated with reference to the projection of males in Halifax County for 1982:

	PC = Base male population, June, 1981	=141,265
plus	B = estimated live male births	+ 2,294
minus	D = estimated male deaths	- 1,219
plus	M = estimated male net migration	-101
equals	Pe = estimated male population, June 1982	142,239

The population model utilized to carry out the present projections implements the methodology described above by performing a series of operations or steps upon a base year population (1981 initially), disaggregated by sex and single year of age (i.e., by cohort). This procedure is summarized in Figure 1.

Step 1 - The population in each age group (differentiated by sex) is moved forward one year in time by multiplying the number of people in each group by the probability of surviving to the next age group (e.g., from age 7 in 1981 to age 8 in 1982). This step determines the number of survivors in each cohort in year X + 1 (where X = the base year) for the ages 1 and above.

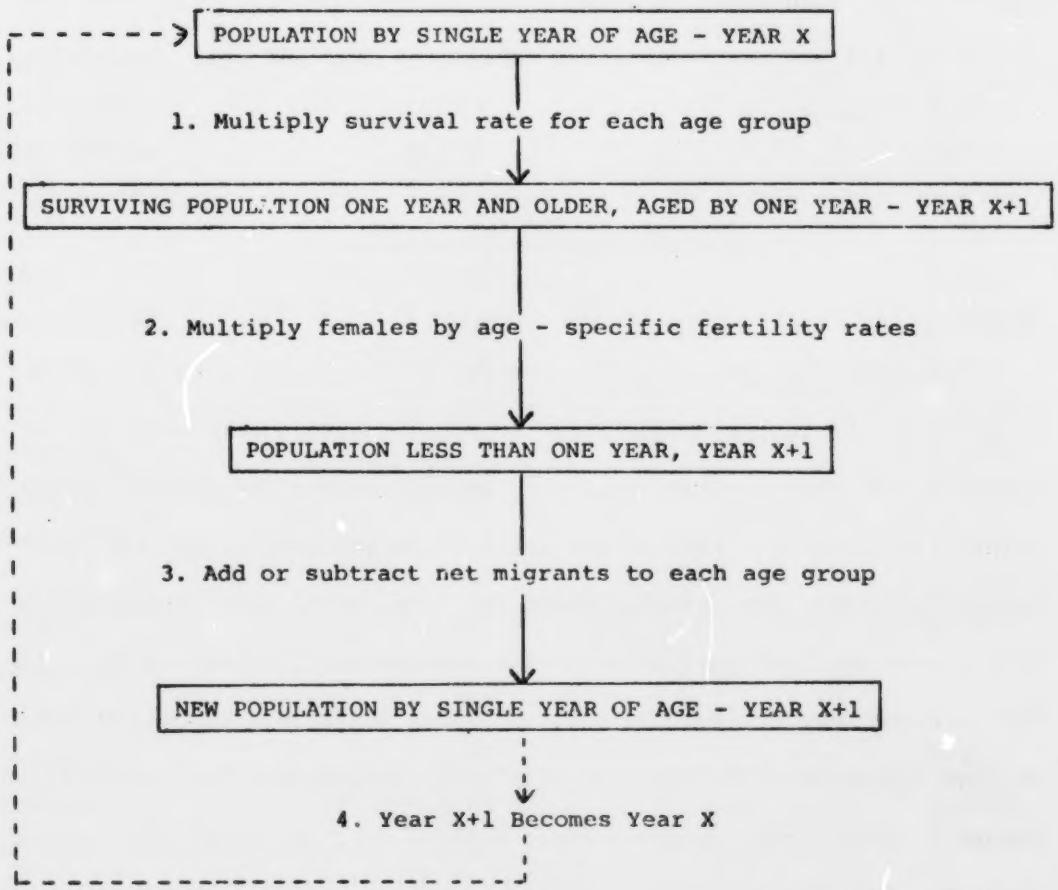
Step 2 - Births in year X + 1 are calculated by multiplying the number of women in each five-year age group between 15-19 and 45-49 inclusive by age-specific fertility rates. Births are distributed by sex by applying a male/female ratio to total births.

Step 3 - Over the period from year X to year X + 1 people will have migrated into and out of the area in question. Thus, net

FIGURE 1

COHORT - SURVIVAL PROJECTION METHOD

(For Each Sex, For Each County)



POPULATION BY SINGLE YEAR OF AGE - YEAR X
1. Multiply survival rate for each age group
SURVIVING POPULATION ONE YEAR AND OLDER, AGED BY ONE YEAR - YEAR X+1
2. Multiply females by age - specific fertility rates
POPULATION LESS THAN ONE YEAR, YEAR X+1
3. Add or subtract net migrants to each age group
NEW POPULATION BY SINGLE YEAR OF AGE - YEAR X+1
4. Year X+1 Becomes Year X

migrants (in-migrants minus out-migrants) are added to the population in each cohort in order to derive the total age/sex distribution in year X + 1. Migration is calculated as a residual by subtracting an expected population from an actual population.

Step 4 - The population of year X + 1 becomes the base population and the process is repeated until the end of the projection period.

Assumptions and Data Inputs

Mortality

Mortality is determined by the use of life table survival rates. Since it is the survived population from the previous year that is of interest in the projections, the actual number of deaths was not determined directly. Instead the actual survived population for each geographic area for single years of age by sex was determined by multiplying the base population by the appropriate survival rates. In the present projections the survival rates applicable to the Province of Nova Scotia in 1975-1977 are utilized throughout the projection period.[2] Since the general Nova Scotia survival rates vary across counties, the survival rates applied to each county were adjusted individually so as to replicate the number of deaths observed during the period 1976-1981. These adjustments are shown in Table 3.

Halifax CMA	1.048	0.960

Fertility

In view of the relatively stable fertility rates in the Province of Nova Scotia, these projections assume that the age-specific fertility rates observed in 1980 will continue to apply throughout the projection period. Once again, as fertility rates vary across counties, those rates applied to individual counties were adjusted so as to more closely track the observed number of births that occurred in each county during the period 1976-1981. These adjustments are shown in Table 3 and the unadjusted Nova Scotia age-specific fertility rates are presented in Table 4.

TABLE 4

Migration

The population projections contained in this report are based upon the assumption that the generally high rates of out-migration which

have historically characterized Nova Scotia will abate considerably during the projection period. The rationale for this assumption lies in the perceived prospects for economic development in Nova Scotia in the coming decade and in the relative scarcity of employment opportunities in others provinces. The levels of migration that characterized the individual counties over the period 1976-1981 (See Table 2) were adjusted so as to produce a more moderate net migration level. The adjustment factors utilized and the effective net migration rates which resulted are summarized in Table 5.

Projected Population 1982-1991

The projected population by sex, for each year of the projection period is presented in Table 6. Included are projections for each county, the Halifax Metropolitan Area, and Nova Scotia.

The projected components of population change are shown in Table 7 (A and B). Births, deaths and net migration are presented for each geographical unit by sex for the two five-year intervals (1982-86 and 1987-91) of the projection period.

In Table 8, projections of actual population, expected population, and net migration are shown for each county by sex and five-year age group. Output is presented for the years 1984-86 and 1991.

Table 9 presents actual and expected population and net migration for Nova Scotia for the years 1984-1986 and 1991; presentation is by five-year age group and sex. The Nova Scotia population by sex and single year of age is shown in Table 10 for the years 1986 and 1991.

PART TWO - HOUSEHOLD AND FAMILY PROJECTIONS

Introduction

There are two main approaches to the projection of households and families. One is the "cohort" method in which persons or groups formed in a particular period of time are traced through life to ascertain the proportions who have certain relevant characteristics. These characteristics may be concerned with the number of children born to them, their economic activity, household headship, school enrollment, and so forth. Many of the statistics needed to use this method are not available, however, and although it is thought to be superior to other methods it is rarely used.

The other method is the "ratio" method. This approach is based on projections of the total population by specific demographic characteristics. Suitable activity ratios are then applied to the population projections. The simplest ratio method consists of applying the present "total households to total population" ratio to the projected total population. A more widely accepted ratio method is the headship rate method, which utilizes population projections by age and sex. Although it is not possible to directly employ the dynamics of the family life cycle, as in the cohort method, the headship rate method does reflect changes in the composition of the population which affect the size and proportion of families and households.

Methodology

The headship rate is defined as the number of heads of families

(households) per 100 persons in the total population or in some segment of the population. Algebraically:

$$\text{Headship rate } i,j,t = \frac{H(i,j,t)}{P(i,j,t)}$$

where H = number of heads

P = population

i = sex

j = age group

t = time

Since age and sex-specific headship rate information was not yet available from the 1981 Census at the time of this report, a simplified headship calculation has been employed. Total, rather than age and sex-specific, headship rates have been computed for each county by dividing the total number of households (and, in turn, families) by the population 15 years and older in that county. This procedure may be represented as:

$$\text{Headship rate } t = \frac{H(t)}{P(t)}$$

where H = number of heads

P = population 15 years and older

t = time

The headship rates must be projected on the basis of historical

evidence. For both households and families the rate of change of headship rates between 1971 and 1981 was taken as being indicative of the expected rate of change of headship to 1991 (Tables 11 and 12). The headship rates during these periods were generally increasing; therefore the projection of future headship rates has as its underlying assumption gradually rising headship rates. In making the household and family projections the appropriate headship rates were applied to the population 15 years of age and older in each county.

This report employs the Statistics Canada definitions of households and families. A family consists of a husband and wife, with or without unmarried children, or a parent with one or more unmarried children, living in the same dwelling. A household is a person or group of persons occupying one dwelling; it usually consists of a family with or without lodgers, employees, and so forth. A household may consist of two or more families sharing a dwelling or a group of unrelated persons or one person living alone. Every person is a member of a household and there is a one-to-one relationship between households and occupied dwellings.

Household and Family Projections

The projected headship rates have been applied to that portion of the projected county populations that is 15 years of age and older to derive projections of households and families for the years 1982 to 1991 (Tables 13 and 14).
